

K Largest Elements

Given an array **nums** of **N** integers and a positive number **K** ($K < N$), design an algorithm to print the **K** largest elements in the given array.

Note : You can print the K largest element in any order.

Example

Input : **nums** = [60, 50, 10, 20, 30, 40], **K** = 3
Output : { 40, 50, 60 }

==

1st appr : 1. sort all : $n \log n$
2. extract top-k elements : k
 $\frac{n \log n + k}{n \log n + k}$

2nd appr 1. transform array into a maxheap : n
2. extract top-k elements : $k \log n$
 $n + k \log n$

3rd appr 1. insert the 1st k - values into a minheap $\rightarrow k \log k$
2. scan the remaining elements $n-k$ and for each element check if that element is $>$ minheap.top() $\sim$ then do a minheap.pop() and track next element $\rightarrow (n-k)(\log k + \log k)$
3. extract all the elements in the heap $\rightarrow k \log k$

}

$$= k \log k + n \log k - \cancel{k \log k} + \cancel{k \log k}$$

$$= k \log k + n \log k$$

$$\overbrace{k \log k + n \log k} =$$

$$\overbrace{n \log n + k} =$$

$$\overbrace{n + k \log n} =$$

K Largest Elements in a Stream

K Largest Elements in a Stream

Given a **running stream** of integers and a positive integer **K**, design an algorithm to print the **K largest elements** in the stream every time you read a **-1** from the stream.

Note : You can print the K largest element in any order.

Example

Input : [60, 50, 10, -1, 20, 30, -1, 40, -1, ...], K = 3

Output : { 10, 50, 60 }

{ 30, 50, 60 }

{ 40, 50, 60 }

...

10, 50, 60

30, 50, 60

40, 50, 60 ...

Merge K-Sorted Linked List

Given the **K sorted** linked list, design an algorithm to **merge** them such that the merged linked list is also sorted.

$$= 2n + 3n + 4n + \dots + kn$$

$$(1 + 2 + 3 + \dots + k)n$$

$$= 2n + 3n + 4n + \dots$$

$$= n(2 + 3 + 4 + \dots + k)$$

$$\sim \frac{k(k+1)}{2} \sim k^2$$

$$= \underline{\underline{nk^2}}$$

$k=3$

$$kn(\underbrace{\log k + \log k}_{\sim \log k})$$

$$= nk \log k$$

Merge K-Sorted Arrays

Given the **K sorted** arrays, design an algorithm to **merge** them such that the merged array is also sorted.

Example

Input

	0	1	2	3
0	1	3	7	10
1	2	4	5	11
2	0	6	8	9

Output

0	1	2	3	4	5	6	7	8	9	10	11
---	---	---	---	---	---	---	---	---	---	----	----

Reorganize String

Given a string, design an algorithm to check if the characters of the given string can be **reorganized** in a way that **no two characters** with the **same value are adjacent** to each other.

Example

Input : "aab"

Input : "aabca"

Input : "aaab"

Median of a Running Stream

Given a running stream of integers, design an algorithm to print the **median** of the numbers in the stream each time a new integer is added to the stream.

Example

Input

Stream	4	6	2	5	3	1	7	9	8	...
Median	4	5	4	4.5	4	3.5	4	4.5	5	...

⇒ HashTable / HashMap

It is a **data structure** which is used to store a collection of **key-value pairs**.

Key	Value
word ₁	→ m ₁
word ₂	→ m ₂
word ₃	→ m ₃
⋮	⋮
word _n	→ m _n

↓

(key)	(value)
food item	→ price
loke	→ ₹40
maggi	→ ₹50
tea	→ ₹20
coffee	→ ₹100
⋮	⋮

(key)	(value)
person name	→ number
p ₁	→ p _{h1}
p ₂	→ p _{h2}
⋮	⋮
p _n	→ p _{hn}

Why use a HashTable ?

HashTable, as a data-structure supports **very efficient lookup operation**.

map <	
insert	worst case $O(\log n)$
erase	
find	

efficient lookup operation.

unordered_map <7

insert
erase
find

on avg.
 $O(1)$

Reason behind Efficiency ?

Data is stored in a HashTable in an **unordered-way**.

HashTable Implementation

Example

Key	Value
0	0
1	1
2	4
3	9
4	16

$n \Rightarrow$ capacity of hash-table
 $m \Rightarrow$ size of hash table

$n = 5$

0	1	2	3	4
1	1	1	1	1
0	1	4	9	16

internal view

(i, i^2)
 $\downarrow$
 $arr[i] = i^2$
 time: $O(1)$

key = i
↓
ret arr[i]
time: $O(1)$

Key = i
↓
arr[i] = -1
~~~~~  
Time:  $O(1)$

Logical View  
Limitations

- Keys are integer values that **exceed** the valid range of indices.
- Keys are **non-integer values**, e.g. strings

To solve this problem, we use a **hash function** - a mathematic function that transforms the keys into a valid index inside the hash table a.k.a hash index.

### Example

| Key | Value |
|-----|-------|
| 9   | 0     |
| 7   | 49    |
| 9   | 81    |
| 6   | 36    |
| 8   | 64    |

$n = 5$

| 0            | 1            | 2            | 3            | 4            |
|--------------|--------------|--------------|--------------|--------------|
| <del>1</del> | <del>1</del> | <del>1</del> | <del>1</del> | <del>1</del> |
| 0            | 36           | 49           | 64           | 81           |

$$h_f \Rightarrow \underline{\text{key} \neq n}$$
$$\therefore |z| = i^2$$

time:  $O(2)$

key = i  
↓  
1/n  
↓  
hashid × -1

time: O(1)

### Limitations

- Multiple (key, value) pairs can be mapped to the same index - **collision**

### Example

| Key | Value |
|-----|-------|
| 0   | 0     |
| 7   | 49    |
| 9   | 81    |
| 6   | 36    |

|   |    |    |    |    |
|---|----|----|----|----|
| 0 | 1  | 2  | 3  | 4  |
| 0 | 36 | 49 | -1 | 81 |

$\frac{0}{100} = \frac{36}{100} = \frac{49}{100} = \frac{-1}{100} = \frac{81}{100}$

## Handling Collision

- Closed Hashing or Open Addressing
  - Linear Probing
  - Quadratic Probing
  - Double Hashing

- Open Hashing or **Chaining**

The idea behind **chaining** is to maintain a **linked list** at each index ( or **bucket** ) of the hash table to store **all** the (key, value) pairs that have been **mapped** to that index.

| Key | Value |
|-----|-------|
| 0   | 0     |
| 7   | 49    |
| 8   | 64    |
| 6   | 36    |
| 2   | 4     |

insert:

Key = i      Val = i<sup>2</sup>

hf [ / n ] const

arr [ hashidx ]

ll  
insert a new node  
in ll maintained  
at hashidx with the  
given key, value

3

$n$  buckets

(m) key, value

$\frac{m}{n}$  ideal size of each bucket

key  
↓  
hf [XN] const ==  
↓  
arr [hashidx]  
↓  
ll  
==  
Search for h  
in the ll  
whose key  
given

## Rehashing

The idea behind rehashing is to **double the capacity** of hash table once the **load factor  $M/N$**  exceeds a certain **threshold**.

### How ?

By creating a new hash table with twice the capacity of the current hash table and **rehashing** (key, value) pairs from current hash table to the new hash table. This way we can **lower the load factor** & **improve the efficiency** of operations on hash table.

We will internally represent the hash table using a **dynamic array of singly linked lists** such each **node of the linked list** present at the  $i^{th}$  ( $0 \leq i \leq N-1$ ) index of the hash table contains a **(key, value)** pair that was hashed/mapped to the  $i^{th}$  index of the hash table.

key  
e node  
at hashidx  
matches  
time  $\propto$  len of  
list at  
hashidx

`int * ptr = new int[N];`

`ListNode * t = new ListNode[N];`
